21st March 2013 (Thursday)**Total Intravenous Anaesthesia (TIVA)**

TIVA can be defined as a technique of general anaesthesia that uses a combination of agents given solely by the intravenous route without simultaneous administration of any inhalational agent except for oxygen and air.

The use of TIVA is made possible because of two main reasons. Firstly the pharmacokinetic and pharmacodynamic properties of modern drugs like propofol and newer synthetic short-acting opioids like remifentanyl.

Secondly, new concepts in pharmacokinetic modelling and advances in computer technology resulting in specialized infusion pumps have made TIVA user friendly hence recently there has been a surge in its usage. A team of experts in the field of paediatric anaesthesia will provide hands-on clinical training during this workshop to show us that TIVA for paediatric patients can be administered with confidence and that this method can be widely used in daily clinical practice.
